On Hammerstein Equations
with Natural Growth Conditions

V. Moroz and P. Zabreiko

Abstract. In this paper we study a nonlinear Hammerstein integral equation by means of the direct variational method. Under certain "natural" growth conditions on the non-linearity we show that the existence of a local minimum for the energy functional implies the solvability of the original equation. In these settings the energy functional may be non-smooth on its domain and, moreover, operators in data may be non-compact. Some solvability and non-trivial solvability results for the original equation are given.

Keywords: *Hammerstein equations, direct variational method, non-smooth functionals*

1. Introduction

In this paper we study the solvability of the nonlinear Hammerstein integral equation

$$x(t) = \int_\Omega k(t,s)f(s,x(s))\,ds \tag{1}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain, $k(t,s) : \Omega \times \Omega \to \mathbb{R}$ is a measurable, symmetric kernel and $f(s,u) : \Omega \times \mathbb{R} \to \mathbb{R}$ is a Carathéodory function. We denote by

$$F(s,u) = \int\limits_0^u f(s,\xi)\,d\xi$$

the primitive of f (note that $F(s,0) \equiv 0$). In what follows $L_p = L_p(\Omega, \mathbb{R})$ stands for the Lebesgue space with the usual norm $\|\cdot\|_{L_p}$, $p' = \frac{p}{p-1}$ for the index conjugate to p, and

$$(x,y) = \int_\Omega x(s)y(s)\,ds$$

for the standard inner product in L_2.

Equation (1) can be rewritten in the operator form

$$x = \mathbf{K}\mathbf{f}x$$

where $\mathbf{f}x(s) = f(s, x(s))$ is the nonlinear superposition operator generated by the function f and $\mathbf{K}$ is the linear integral operator

$$\mathbf{K}x(t) = \int_\Omega k(t, s)x(s)\,ds$$

generated by the kernel k. Hereafter we assume the following:

- $\mathbf{K}$ acts in L_2 and has the norm $\|\mathbf{K}\|$
- $\mathbf{K}$ is positive-definite on L_2, i.e. $(\mathbf{K}x, x) > 0$ for all $0 \neq x \in L_2$.

Since the kernel k is symmetric, $\mathbf{K}$ is selfadjoint in L_2 (see [10] for regular operators and [20] for the general case).

The classical direct variational approach for the treatment of the Hammerstein equation (1) goes back to the early papers by Hammerstein [7] and Golomb [6]. According to these papers the solutions of equation (1) correspond to the minimum of the energy functional φ formed by F and $\mathbf{K}$ in some Hilbert space E. Later, in the work by Rothe [17], Vainberg [19], Krasnosel'skii [9], Zabreiko and Povolotskii [21] the necessity of severe restrictions on the growth of $|f(s, u)|$ and "singularities" of the kernel $k(t, s)$ were clarified. More precisely, the following classical p-growth conditions

for some $p \in [2, +\infty)$ there exist $a_1 > 0$ and $b_1 \in L_{p'}$ such that
$|f(s, u)| \leq a_1|u|^{p-1} + b_1(s)$ and the operator $\mathbf{K}$ acts from $L_{p'}$ into L_p

were imposed. Under these conditions the energy functional φ is of class $\mathcal{C}^1$ on E and its minimum (if it exists) is a solution of the Euler-Lagrange equation $\nabla\varphi(x) = 0$ which is equivalent to the original equation (1). On the other hand, a minimiser for φ still may exist even when φ does not possess any differentiability properties. So it is natural to ask whether it solves the Euler-Lagrange equation for φ in some weak sense. Recently similar questions have been discussed by many authors in the context of classical calculus of variations and quasilinear elliptic boundary value problems (see [2 - 5, 18]). In this paper we introduce (in some sense minimal) *natural growth conditions* under which the existence of a local minimum for φ implies solvability of the Hammerstein integral equation (1). Some preliminary results of this type were obtained by the authors in [12, 14].

The presentation of the material in the paper is given in the following way. In Section 1 we define the energy space E for equation (1) and study some of its properties. In Section 2 we define the energy functional φ on E and prove the existence of minimisers for φ under the usual one-sided coercivity condition on F, without any additional constraints on f or $\mathbf{K}$. In Section 3 we introduce the natural growth conditions under which the existence of a local minimum for φ implies the solvability of the original Hammerstein equation (1). This allows us to obtain in Sections 4 and 5 several solvability and non-trivial solvability results for equation (1). The existence of multiple solutions for equation (1) together with some open problems in this direction are discussed in Section 6.

2. The energy space

In this section we define the energy space E generated by the integral operator $\mathbf{K}$ as well as its dual space. These spaces are well known objects in the general theory of Hilbert scales generated by a linear operator (see [11]). For our further purposes we will also need some additional information about the properties of the energy space E determined by specific properties of the integral operator $\mathbf{K}$.

According to our assumptions the operator $\mathbf{K}$ is bounded, selfadjoint and positive definite in L_2. Let $\mathbf{L}$ be the left inverse to $\mathbf{K}$, that is an unbounded positive definite selfadjoint operator in L_2 with domain $D(L) \subset L_2$ such that $\mathbf{L}\mathbf{K}x = x$ for all $x \in L_2$. We define a positive definite bilinear form on $D(L)$ by means of the formula $\langle x, y \rangle = (x, \mathbf{L}y)$. Clearly, $\langle \cdot, \cdot \rangle$ is an inner product on $D(L)$. We define the Hilbert space E as completion of $D(L)$ with respect to the norm $\| \cdot \| = \langle \cdot, \cdot \rangle^{\frac{1}{2}}$. The space E is said to be the *energy space* for $\mathbf{K}$. We denote by E' the dual energy space obtained by the completion of L_2 with respect to the norm $\|x\|_* = (x, \mathbf{K}x)^{\frac{1}{2}}$.

Lemma 1. *The space E' has the following properties:*

(a) *The conjugate to E space E^* can be identified with the space E': for any $l \in E^*$ there exists $y \in E'$ such that $l(x) = (y, x)$ for all $x \in E$; moreover, $\|l\| = \|y\|_*$.*

(b) $E \cong \mathbf{K}^{\frac{1}{2}}L_2 \cong \tilde{\mathbf{K}}E'$, *where $\mathbf{K}^{\frac{1}{2}}$ is the square root of $\mathbf{K}$, $\tilde{\mathbf{K}}$ is the closure of $\mathbf{K}$ with respect to $\| \cdot \|_*$ and "$\cong$" means an isomorphism.*

(c) $\langle x, x \rangle \geq \|\mathbf{K}\|^{-1}\|x\|_{L_2}^2$ *for all $x \in E$.*

(d) *The embeddings $E \subset L_2 \subset E'$ are continuous and dense.*

Proof. See, for example, [11] ∎

Let us remark that the space E' may contain some "ideal" elements and in general $E' \not\subset S$, where we denote by $S = S(\Omega, \mathbb{R})$ the space of almost everywhere finite Lebesgue-measurable functions on Ω endowed with the topology generated by the convergence in measure. On the other hand, for the space E we have the following remarkable compactness result.

Lemma 2. *The embedding $E \subset S$ is continuous and compact.*

Proof. The proof of the lemma follows immediately from the fact that the square root $\mathbf{K}^{\frac{1}{2}}$ of the integral operator $\mathbf{K}$ is continuous and compact as an operator from L_2 into S (see [21: Lemma 1]). Indeed, suppose that $(x_n) \subset E$ is a bounded sequence in E. By Lemma 1/(b) there exists a bounded sequence $(y_n) \subset L_2$ such that $x_n = \mathbf{K}^{\frac{1}{2}}y_n$. Hence (x_n) contains a subsequence converging in measure to some $x \in E$ ∎

Now suppose that we have some information about the action of the operator $\mathbf{K}$ in the scale L_p. Then we can obtain some additional information about the location of the spaces E and E' with respect to the Lebesgue scale.

Lemma 3. *If for some $p \in [2, +\infty)$ the operator $\mathbf{K}$ acts from $L_{p'}$ into L_p, then the embeddings $E \subset L_p \subset L_2 \subset L_{p'} \subset E'$ are continuous and dense.*

Proof. The proof of the lemma follows from the classical Krasnosel'skii-Krein factorization theorem (see [10]) which states that the square root $\mathbf{K}^{\frac{1}{2}}$ acts from L_2 into L_p

and is continuous. Therefore the embedding $E \subset L_p$ follows immediately from Lemma 1/(b).

Now let us consider the embedding $L_{p'} \subset E'$. Let $y \in L_{p'}$. Clearly, $l(x) = (y, x)$ is a linear continuous functional on $E \subset L_p$ and by Lemma 1/(a) we have $y \in E'$.

The continuity and density of the embeddings follow from the continuity of $\mathbf{K}^{\frac{1}{2}}$ and the fact that the kernel of $\mathbf{K}^{\frac{1}{2}}$ (in L_2) is trivial ∎

2. Existence of a minimum

We define the *energy functional* on E for equation (1) by the formula

$$\varphi(x) = \frac{1}{2}\|x\|^2 - \int_\Omega F(s, x(s))\, ds.$$

It is well-known (see, for example, [1]) that the requirement on φ to be of class $\mathcal{C}^1$ or at least $\mathcal{C}^0$ on E implies severe restrictions on the growth of the function $|F(s, u)|$. Moreover, without additional restriction on the growth of the primitive F the functional φ may be not well-defined on the whole space E. However, since $F(s, 0) = 0$ by definition (and hence $\varphi(0) = 0$) it follows that

$$\mathrm{Dom}\,(\varphi) = \{x \in E : |\varphi(x)| < \infty\} \neq \emptyset.$$

In this section we are interested in the investigation of conditions which imply the existence of a minimum for φ. According to the classical Weierstrass principle (see, for example, [18, 19]) it suffices to verify that φ is (sequentially) lower semicontinuous with respect to the weak topology on E and coercive, that is $\varphi(x) \to +\infty$ as $\|x\| \to \infty$. Let F satisfy the usual one-sided *coercivity condition*

($\mathcal{A}$) There exist $a < \|\mathbf{K}\|^{-1}$, $b \in L_1$ and $y \in E'$ such that $F(s, u) - y(s)u \leq \frac{a}{2}u^2 + b(s)$

where $y \in E'$ means that $l(x) = (y, x)$ is a linear continuous functional on E. We assert that under condition ($\mathcal{A}$) the functional φ attains its infimum.

Lemma 4. *Let the coercivity condition ($\mathcal{A}$) be satisfied. Then φ is bounded from below and coercive.*

Proof. Condition ($\mathcal{A}$) and Lemma 1/(c) imply

$$\varphi(x) \geq \frac{1}{2}\|x\|^2 - \int_\Omega \left\{\frac{a}{2}x^2(s) + b(s)\right\} ds - \int_\Omega y(s)x(s)\, ds$$

$$= \frac{1}{2}\left(\|x\|^2 - a\|x\|_{L_2}^2\right) - \|b\|_{L_1} - (y, x)$$

$$\geq \frac{1}{2}\left(1 - a\|\mathbf{K}\|\right)\|x\|^2 - \|b\|_{L_1} - \|y\|_*\|x\|$$

$$\to +\infty$$

as $\|x\| \to +\infty$ ∎

Lemma 5. *Let the coercivity condition* $(\mathcal{A})$ *be satisfied. Then* φ *is (sequentially) lower semi-continuous in the weak topology on* E.

Proof. The energy functional φ can be rewritten in the form

$$
\begin{aligned}
\varphi(x) &= \frac{1}{2}\|x\|^2 - \int_\Omega F(s, x(s))\, ds \\
&= \frac{1}{2}\|x\|^2 - \int_\Omega \left\{\frac{a}{2}x^2(s) + b(s)\right\} ds + \int_\Omega y(s)x(s)\, ds \\
&\quad + \int_\Omega \left\{\frac{a}{2}x^2(s) + b(s) - \left\{F(s, x(s)) - y(s)x(s)\right\}\right\} ds \\
&= \left\{\frac{1}{2}\|x\|^2 - \frac{a}{2}\|x\|^2_{L_2}\right\} - \|b\|_{L_1} - (y, x) \\
&\quad + \int_\Omega \left\{\frac{a}{2}x^2(s) + b(s) - \left\{F(s, x(s)) - y(s)x(s)\right\}\right\} ds.
\end{aligned}
$$

Let us consider herein each term separately. We have by condition $(\mathcal{A})$ and Lemma 1/(c)

$$
\frac{1}{2}\|x\|^2 - \frac{a}{2}\|x\|^2_{L_2} \geq \frac{1}{2}(1 - a\|\mathbf{K}\|)\|x\|^2 \geq 0 \qquad \text{for all} \quad x \in E.
$$

Hence the quadratic term is (sequentially) weakly lower semicontinuous as a positive definite form on E (see [19]). The linear term (y, x) is also weakly continuous on E.

Now let us consider the last term

$$
\psi(x) = \int_\Omega \left\{\frac{a}{2}x^2(s) + b(s) - \left\{F(s, x(s)) - y(s)x(s)\right\}\right\} ds.
$$

Let $(x_n) \subset \mathrm{Dom}\,(\varphi)$ be weakly converging to x_0. Then the sequence

$$
u_n(s) = \frac{a}{2}x_n^2(s) + b(s) - \left\{F(s, x_n(s)) - y(s)x_n(s)\right\}
$$

converges to

$$
u_0(s) = \frac{a}{2}x_0^2(s) + b(s) - \left\{F(s, x_0(s)) - y(s)x_0(s)\right\}
$$

in measure. From condition $(\mathcal{A})$ it follows that the sequence (u_n) is non-negative. Now applying the Fatou lemma we obtain

$$
\int_\Omega u_0(s)\, ds \leq \liminf_{n \to \infty} \int_\Omega u_n(s)\, ds
$$

which means that ψ is (sequentially) weakly lower semicontinuous ∎

Theorem 1. *Let the coercivity condition* $(\mathcal{A})$ *be satisfied. Then* φ *is bounded from below and attains its infimum on each non-empty weakly closed set* $\mathcal{M} \subseteq E$.

Proof. The proof of the theorem follows from Lemmas 4 and 5 ∎

Remark 1. There are many well-known results of this sort (see, for example, [9, 21]). In contrast to the previous results we do not need any compactness-type assumptions on the operator **K** or primitive F (see [21] for the discussion of these conditions in connection with standard p-growth conditions). The "compactness" of the variational problem follows from the measure-compactness of integral operators in L_2 (Lemma 3).

Remark 2. The restriction $a < \|\mathbf{K}\|^{-1}$ in the coercivity condition $(\mathcal{A})$ can be slightly relaxed using the method developed by A. M. Krasnosel'skii which is based on some delicate integral inequalities (see [8] for a discussion).

3. Natural growth conditions

In this section we are interested in minimal conditions on the operator **K** and nonlinearity f which ensure that each point of local minimum of φ corresponds to a solution of the Hammerstein equation (1). We say that the *natural (p,q)-growth conditions* for equation (1) are satisfied if for some $p \geq 2$ and $q \geq p$

$(\mathcal{A}_1)$ **K** acts from $L_{p'}$ into L_p

$(\mathcal{A}_2)$ **K** acts from L_∞ into L_q

$(\mathcal{A}_3)$ There exists $a_1 > 0$, $b_1 \in L_{q'}$ such that $|f(s,u)| \leq a_1|u|^{\frac{p}{q'}} + b_1(s)$.

Clearly, in the case $q = p$ the conditions $(\mathcal{A}_1) - (\mathcal{A}_3)$ coincide with the classical p-growth conditions guaranteeing that the energy functional φ is of class $\mathcal{C}^1$ on E. However, if $q > p$, then in general the functional φ need not be differentiable on E. Moreover, in this case in general $\mathrm{Dom}\,(\varphi) \subset E$. Nevertheless, if we confine ourselves to a restricted class of "test functions" from E, it is possible to derive necessary conditions of the extremum in the form of the Euler-Lagrange equation. This class must be so small to agree with the growth of $|f(s,u)|$. On the other hand, it must be sufficiently large to ensure the "necessary conditions" for the solvability of equation (1). We will show that under the (p,q)-growth conditions $(\mathcal{A}_1) - (\mathcal{A}_3)$ both requirements are satisfied for φ by the functions from the *test space* $T = \mathbf{K}L_\infty$. By condition $(\mathcal{A}_2)$ it follows that $T \subset L_q$. By Lemma 1/(b) and (d), $L_\infty \subset L_2 \subset E'$ and hence $T = \mathbf{K}L_\infty \subset E$.

Lemma 6. *Let the (p,q)-growth conditions $(\mathcal{A}_1) - (\mathcal{A}_3)$ be satisfied and $p \geq 2$, $q \geq p$. Then for any $x \in \mathrm{Dom}\,(\varphi)$ and each $h \in T$ there exists the variation*

$$\delta\varphi(x,h) = \frac{d}{d\tau}\varphi(x+\tau h)|_{\tau=0} = \langle x, h\rangle - \int_\Omega f(s,x(s))h(s)\,ds. \qquad (2)$$

Proof. Set
$$\psi(x) = \int_\Omega F(s,x(s))\,ds.$$

Clearly, $\mathrm{Dom}\,(\psi) = \mathrm{Dom}\,(\varphi)$. By the mean value theorem for each $x \in \mathrm{Dom}\,(\varphi)$ and $h \in T$ there exists a function θ such that $0 \leq \theta(s) \leq 1$ and

$$\frac{\psi(x+\tau h) - \psi(x)}{\tau} = \int_\Omega f\big(s, x(s) + \tau\theta(s)h(s)\big)h(s)\,ds. \qquad (3)$$

It is known [21] that the function θ may be chosen to be measurable so $\theta \in L_\infty$ and the right-hand side of (3) has sense.

We shall verify that the integral in the right-hand side of (3) does exist. From condition $(\mathcal{A}_1)$ by Lemma 3 it follows that $E \subset L_p$ and hence we have for $\tau \in \mathbb{R}$ that $x + \tau\,\theta\,h \in L_p$. Further, from condition $(\mathcal{A}_3)$ it follows that the superposition operator $\mathbf{f}$ maps L_p into $L_{q'}$ (see, for example, [1]) and hence $f\big(\cdot, x(\cdot) + \tau\,\theta(\cdot)h(\cdot)\big) \in L_{q'}$. Since $h \in T$ it follows that $f\big(\cdot, x(\cdot) + \tau\,\theta(\cdot)h(\cdot)\big)h(\cdot) \in L_1$ that is the integral in the right-hand side of (3) does exist.

Let $|\tau| \le 1$ and $\tau \to 0$. Clearly, $x(s) + \tau\,\theta(s)h(s) \to x(s)$ in measure, and there exists $u \in L_p$ such that $|x(s) + \tau\,\theta(s)h(s)| \le u(s)$ for all $\tau \in [-1, 1]$. So the Lebesgue dominated convergence theorem can be applied to (3) and we have

$$
\begin{aligned}
\delta\psi(x, h) &= \frac{d}{d\tau}\varphi(x + \tau h)|_{\tau=0} \\
&= \lim_{\tau \to 0} \frac{\psi(x + \tau h) - \psi(x)}{\tau} \\
&= \lim_{\tau \to 0} \int_\Omega f\big(s, x(s) + \tau\,\theta(s)h(s)\big)h(s)\,ds \\
&= \int_\Omega f\big(s, x(s)\big)h(s)\,ds.
\end{aligned}
$$

This implies (2) since the term $\frac{1}{2}\|x\|^2$ is smooth on E ∎

Now we proceed to the main result of the section.

Theorem 2. *Let the (p, q)-growth conditions $(\mathcal{A}_1) - (\mathcal{A}_3)$ be satisfied and $p \ge 2$, $q \ge p$. Then each local minimum $x^* \in \mathrm{Dom}\,(\varphi)$ of φ is a solution of the Hammerstein equation* (1).

Proof. Let $x^* \in \mathrm{Dom}\,(\varphi) \subset E \subset L_p$ be a minimum of φ. By Lemma 6 the variation $\delta\varphi(x^*, h)$ with respect to $h \in T$ exists. Moreover, since x^* is a local minimum of φ on E it follows that $\delta\varphi(x^*, h) = 0$ for all $h \in T$. By the definition of the inner product $\langle\cdot, \cdot\rangle$ we have

$$
\delta\varphi(x^*, h) = \langle x^*, h\rangle - \int_\Omega f(s, x^*(s))h(s)\,ds = (\mathbf{L}x^*, h) - (\mathbf{f}x^*, h) = 0
$$

for all $h \in T$. Since $T = \mathbf{K}L_\infty$ and the kernel of $\mathbf{K}$ on L_∞ is trivial the operator $\mathbf{K}$ is one-to-one between L_∞ and T. Hence we can write

$$
\delta\varphi(x^*, h) = (\mathbf{L}x^*, \mathbf{K}g) - (\mathbf{f}x^*, \mathbf{K}g) = 0 \qquad \text{for all} \ \ g \in L_\infty.
$$

Bearing in mind that $\mathbf{f}x^* \in L_{q'}$ by condition $(\mathcal{A}_3)$, $\mathbf{K}\mathbf{f}x^* \in L_1$ by condition $(\mathcal{A}_2)$ and the kernel $k(t, s)$ is symmetric, one can easily see that $x^* - \mathbf{K}\mathbf{f}x^* \in L_1$. Hence by the definition of $\mathbf{L}$ we obtain

$$
\delta\varphi(x^*, h) = (\mathbf{K}\mathbf{L}x^*, g) - (\mathbf{K}\mathbf{f}x^*, g) = (x^* - \mathbf{K}\mathbf{f}x^*, g) = 0
$$

for all $g \in L_\infty$ or, in other words, $x^* \in L_p$ is a solution of the original Hammerstein equation (1) ∎

Remark 3. Clearly, our choice of T as "test" space for φ is not the only possible. For example, we can choose as "test" space some "weighted" space L_{∞, u_0} with weight u_0 compatible with the singularities of the kernel $k(t, s)$ or the subspace of E generated by the eigenfunctions of **K** etc. (see [14] for an abstract approach and details).

4. Existence of the solution

Basic existence results for the Hammerstein equation (1) follow immediately from Theorems 1 and 2.

Theorem 3. *Let the coercivity condition* $(\mathcal{A})$ *and the* (p, q)*-growth conditions* $(\mathcal{A}_1)$ $-(\mathcal{A}_3)$ *be satisfied and* $p \geq 2$, $q \geq p$. *Then the Hammerstein equation* (1) *has at least one solution in* L_p.

Remark 4. The result seems to be new even in the case $q = p$ (that is the case of the classical p-growth condition). In contrast to previous results of this sort we do not need any compactness-type restriction on **K** or f (cf. Remark 1).

Remark 5. Let $\mathcal{L}(\mathbf{K})$ be the set of all pairs $(\alpha, \beta) \in [0, 1] \times [0, 1]$ such that the operator **K** acts from $L_{\frac{1}{\alpha}}$ into $L_{\frac{1}{\beta}}$. Following [10] we call $\mathcal{L}(\mathbf{K})$ the $\mathcal{L}$-*characteristic* of **K**. Since the kernel $k(t, s)$ is symmetric the set $\mathcal{L}(\mathbf{K})$ is always symmetric with respect to the line $\alpha + \beta = 1$. Since $L_{\frac{1}{\alpha_1}} \subseteq L_{\frac{1}{\alpha_2}}$ for $\alpha_1 \leq \alpha_2$, the set $\mathcal{L}(\mathbf{K})$ contains along with any points (α, β) the rectangle $\mathrm{co}\,\{(\alpha, \beta), (\alpha, 1), (0, \beta), (0, 1)\}$. Moreover, the Riesz-Thorin interpolation theorem [10] states that the $\mathcal{L}$-characteristic $\mathcal{L}(\mathbf{K})$ is always a convex set. Figures 1 and 2 present the $\mathcal{L}$-characteristic of **K** under the classical p-growth condition and the natural (p, q)-growth conditions, respectively.

Remark 6. A typical example of a function f satisfying the natural (p, q)-growth conditions and not satisfying the classical p-growth conditions is given by

$$f(s, u) = |u|^{\frac{p}{q'}} + y(s)$$

with $q > p$ and $y \in L_{p'}$. Non-linearities of a different sort are given by functions f with the bounded primitive $F(s, u) = \sin(u^{\frac{p}{q'}})$. In this case the energy functional φ is continuous on E but if $q > p$, then it is nowhere differentiable on E in the classical sense. This is also the case for the primitive $F(s, u) = \sin(b(s)u)$ with $b \in L_{q'}$ and $b \notin L_{p'}$ but in this case the growth on s is essential. However, we note that in the case of the non-homogeneous equation

$$f(s, u) = g(s, u) - y(s)$$

with $g(s, 0) \equiv 0$ we can not relax the restriction on the s-singularity of y. In view of condition $(\mathcal{A})$, y should belong to $L_{p'}$ since $L_{p'} \subset E'$.

As an example of an application of Theorem 3 let us consider the Dirichlet boundary value problem

$$\left.\begin{array}{ll} -\Delta u = g(u) + y(s) & \text{in } \Omega \\ u = 0 & \text{on } \partial\Omega \end{array}\right\} \tag{4}$$

where $\Omega \subset \mathbb{R}^N$ is an open bounded domain with a smooth boundary and g is a continuous function satisfying the condition $g(0) = 0$. We denote by λ_1 the first eigenvalue of the Laplacian $-\Delta$ on Ω. It is known that in the case when $y \in L_{\frac{N}{2}}$ the solutions of problem (4) belong to L_∞. Therefore, under the one-sided condition $u\, g(u) \leq a\, u^2 + b$ for some $a < \lambda_1$ and $b \in \mathbb{R}$ the special truncation procedure (based on a priory estimates for problem (4) and the weak maximum principle for $-\Delta$) can be applied. As a result, when using variational methods we do not need any condition on the growth of g for the treatment of (4). Moreover, the energy functional corresponding to problem (4) is of class $\mathcal{C}^1$ (see, for example, [18]).

Let us consider the case of a singular right-hand term $y \in L_{\frac{2N}{N+2}}$. It is known (see [10]) that problem (4) is equivalent to the Hammerstein equation (1) with the kernel $k(t, s)$ generated by the Green function for the Laplacian $-\Delta$ on Ω. The classical growth conditions lead to the $\frac{N+2}{N-2}$-growth of g. Using Theorem 3 with $p = \frac{2N}{N-2}$ and $q = \infty$ we obtain the following result.

Theorem 4. *Let there exist $a < \lambda_1$ and $b \in \mathbb{R}$ such that $\int_0^t g(\xi)\, d\xi \leq \frac{a}{2}\, u^2 + b$ and let there exist $a_1, b_1 \in \mathbb{R}$ such that $|g(u)| \leq a_1 |u|^{\frac{2N}{N-2}} + b_1$. Then for each $y \in L_{\frac{2N}{N+2}}$ problem (4) has at least one solution in the Sobolev space $\mathbf{H}_0^1(\Omega)$.*

Proof. The proof ollows from Theorem 3 and the Sobolev embedding theorems ∎

Remark 7. A similar problem for (4) was considered in [5]. Using the method of sub- and super-solutions the authors proved the existence of a solution of problem (4) in the case $y \in L_\infty$ under a one-sided coercivity condition $(\mathcal{A})$ and without any additional assumptions on the growth of g. See also [3, 4] or further results in this direction based on special technique of partial differential equations.

5. Existence of a non-trivial solution

Henceforth we assume that $f(s,0) \equiv 0$, so we are interested in the existence of a non-trivial solution of equation (1). More precisely, in the rest of the paper we assume that the function f is of the special form

$$f(s,u) = \alpha\, u + g(s,u) \qquad \text{for some } \alpha \in \mathbb{R}$$

with g satisfying the condition

$(\mathcal{A}_3)'$ For each $\varepsilon > 0$ there exists $a_\varepsilon > 0$ and $b_\varepsilon \in L_{\frac{p+q'}{p-q'}}$ with $\|b_\varepsilon\|_{L_{\frac{p+q'}{p-q'}}} < \varepsilon$ such that

$$|g(s,u)| \le a_\varepsilon |u|^{\frac{p}{q'}} + b_\varepsilon(s)|u|.$$

This condition is stronger than condition $(\mathcal{A}_3)$. We rewrite the energy functional φ in the form

$$\varphi(x) = \frac{1}{2}\mathcal{E}_\alpha(x) - \psi(x)$$

where

$$\mathcal{E}_\alpha(x) = \|x\|^2 - \alpha\|x\|_{L_2}^2, \quad \psi(x) = \int_\Omega G(s,x(s))\,ds, \quad G(s,u) = \int_0^u g(s,\xi)\,d\xi.$$

Clearly, $\mathcal{E}_\alpha$ is a continuous form on E. We will show that $\mathcal{E}_\alpha$ is the second variation of the energy functional φ at zero with respect to some reasonable class of "test functions" from E. In contrast to the test space T we do not need this class to be sufficiently large. As we will see in the following for this class it suffices to contain only the first eigenfunction of $\mathbf{K}$.

Lemma 7. *Let the (p,q)-growth conditions $(\mathcal{A}_1), (\mathcal{A}_2)$ and $(\mathcal{A}_3)'$ be satisfied and $p > 2$, $q \ge p$. Then for each $h \in E \cap L_{\frac{p}{q'}+1}$ there exists the second variation of φ at zero*

$$\delta^2\varphi(0,h) = \frac{d^2}{d\tau^2}\,\varphi(\tau h)|_{\tau=0} = \mathcal{E}_\alpha(h). \tag{5}$$

Proof. From condition $(\mathcal{A}_3)'$ it follows that for each $\varepsilon > 0$ there exists $a_\varepsilon > 0$ and $b_\varepsilon \in L_{\frac{p+q'}{p-q'}}$ with $\|b_\varepsilon\|_{L_{\frac{p+q'}{p-q'}}} < \varepsilon$ such that $|G(s,u)| \le a_\varepsilon |u|^{\frac{p}{q'}+1} + b_\varepsilon(s)|u|^2$. Hence we obtain for $h \in E \cap L_{\frac{p}{q'}+1}$ (using the Hölder inequality)

$$|\psi(\tau h)| \le a_\varepsilon \tau^{\frac{p}{q'}+1} \int_\Omega |h(s)|^{\frac{p}{q'}+1} ds + \tau^2 \int_\Omega b_\varepsilon(s)|h(s)|^2 ds \le c_1 a_\varepsilon \tau^{\frac{p}{q'}+1} + c_2 \varepsilon^{\frac{p-q'}{p+q'}} \tau^2$$

with $c_1, c_2 > 0$ depending only on h. Since $\frac{p}{q'}+1 > 2$ and ε is arbitrarily small we have $\lim_{\tau\to 0} \frac{\psi(\tau h)}{\tau^2} = 0$ which proves the lemma ∎

Observe that in the case $p > 2$ the operator $\mathbf{K}$ acts from $L_{p'}$ into $L_p \subset L_2$ and hence $\mathbf{K}$ is compact in L_2 [10]. We denote by

$$\lambda_1 \ge \lambda_2 \ge \ldots \lambda_k \ge \ldots > 0$$

the eigenvalues of $\mathbf{K}$ in L_2 and by $(e_k) \subset L_2$ the corresponding eigenfunctions. We will show that our assumptions imply some additional regularity of these eigenfunctions.

Lemma 8. *Let the (p,q)-growth conditions $(\mathcal{A}_1)$ and $(\mathcal{A}_2)$ be satisfied and $p > 2$, $q \geq p$. Then $(e_k) \subset E \cap L_r$ for each $r < r^* = \frac{q(p-2)+p}{p-1}$.*

Proof. By conditions $(\mathcal{A}_1)$ and $(\mathcal{A}_2)$, the operator $\mathbf{K}$ acts from $L_{p'}$ into L_p and from L_∞ into $L_{q'}$. The Riesz-Thorin interpolation theorem [10] states that for $\tau \in [p', \infty]$ the operator $\mathbf{K}$ acts from L_τ into L_r with

$$\frac{1}{r} = \frac{p-q}{q(p-1)}\frac{1}{\tau} + \frac{1}{q}.$$

Let $r^* > 2$ be the solution of the equation

$$\frac{1}{r} = \frac{q-p}{q(p-1)}\frac{1}{r} + \frac{1}{q}, \qquad \text{that is} \quad r^* = \frac{q(p-2)+p}{p-1}.$$

Hence for each $r < r^*$ there exists $n \in \mathbb{N}$ such that $\mathbf{K}^n$ acts from L_2 into L_r (see Figure 2 for the "visualization" of the number r^*). Let $e_k \in L_2$ be an eigenfunction of $\mathbf{K}$. Iterating e_k by $\mathbf{K}$ we obtain $(\lambda_k)^n e_k = \mathbf{K}^n e_k$ and hence $e_k \in E \cap L_r$ for each $r < r^*$ ∎

Theorem 5. *Let the coercivity condition $(\mathcal{A})$ and the (p,q)-growth conditions $(\mathcal{A}_1)$, $(\mathcal{A}_2)$ and $(\mathcal{A}_3)'$ be satisfied and $p > 2$, $q > \max\{p, \frac{p-1}{p-2}\}$. Then for each $\alpha > \lambda_1^{-1}$ the Hammerstein equation (1) has at least one non-trivial solution in L_p.*

Proof. The existence of a minimum for φ follows from condition $(\mathcal{A})$ by Theorem 1. Since $q > \max\{p, \frac{p-1}{p-2}\}$ we have

$$\frac{p}{q'} + 1 < r^* = \frac{q(p-2)+p}{p-1}.$$

Hence by Lemma 8 the eigenfunctions of $\mathbf{K}$ belong to $L_{\frac{p}{q'}+1}$ and by Lemma 7 the second variation of φ with respect to the eigenfunctions (e_k) does exist. Consider e_1 as a test function. We obtain

$$\delta^2\varphi(0, e_1) = \mathcal{E}_\alpha(e_1) = (\lambda_1^{-1} - \alpha)\|e_1\|_{L_2} < 0.$$

This means that zero is not a local minimum for φ and hence φ attains its minimum at some point x different from zero. Therefore Theorem 2 implies that $x \neq 0$ is a solution of equation (1) ∎

Remark 8. Clearly, in the statement of the theorem we have $\max\left\{p, \frac{p-1}{p-2}\right\} = p$ for $p \geq \frac{3+\sqrt{5}}{2}$, that is the additional restriction on q is required only in the case of "small" p.

Remark 9. For the classical growth conditions an analogous result was established in [22] for more general non-linearities f of the form $f(s, u) = a(s)\,u + g(s, u)$ with $a \in L_{\frac{p}{p-2}}$. In this paper we consider only the simplest case $a(s) \equiv \alpha$. The statement of Theorem 5 can be easily generalized up to the case $a \in L_\infty$. However, in the case of larger singularities of $a(s)$ some additional delicate control on the growth of the primitive $G(s, u)$ is required (see [13] for details).

6. Multiple solutions

In this section we prove a simple multiplicity result for the Hammerstein equation (1).

Theorem 6. *Let the coercivity condition* $(\mathcal{A})$ *and the* (p, q)*-growth conditions* $(\mathcal{A}_1)$, $(\mathcal{A}_2)$ *and* $(\mathcal{A}_3)'$ *be satisfied and* $p > 2$, $q > \max\{p, \frac{p-1}{p-2}\}$. *Then in the case*

$$G(s, u) \leq 0 \tag{6}$$

for each $\alpha \in (\lambda_1^{-1}, \lambda_2^{-1}]$ *the Hammerstein equation* (1) *has at least two non-trivial solutions in* L_p.

Proof. Since $\alpha \in (\lambda_1^{-1}, \lambda_2^{-1}]$ the form $\mathcal{E}_\alpha$ is negative definite on the one-dimensional subspace $E_1 = \mathrm{Span}\{e_1\}$ and non-negative definite on its orthogonal complement in E. Set

$$\mathcal{M}_\alpha^+ = \left\{ h \in E \,|\, \mathcal{E}_\alpha(h) \leq 0 \text{ and } \langle e_1, h \rangle \geq 0 \right\}.$$

Clearly, $\mathcal{M}_\alpha^+$ is convex and closed and hence weakly closed. By Theorem 1, φ attains its infimum on $\mathcal{M}_\alpha^+$ at some point x^+. Since $\alpha > \lambda_1$ and $e_1 \in E \cap L_{\frac{p}{q'}+1}$ by Lemma 7 we have $\delta^2 \varphi(0, e_1) = \mathcal{E}_\alpha(e_1) < 0$ and, since $e_1 \in \mathcal{M}_\alpha^+$, $\inf_{\mathcal{M}_\alpha^+} \varphi = \varphi(x^+) < 0$. Hence $x^+ \neq 0$.

We have to verify that $x^+ \neq 0$ is a local minimum of φ on the whole space E. If so, Theorem 2 implies that x^+ is a non-trivial solution of equation (1). Clearly, it suffices to show that x^+ lies in the interior of the set $\mathcal{M}_\alpha^+$. Suppose that the opposite is true, that is $x^+ \in \partial \mathcal{M}_\alpha^+$. In this case $\mathcal{E}_\alpha(x^+) = 0$ and by (6) we have

$$\varphi(x^+) = \mathcal{E}_\alpha(x^+) - \int_\Omega G(s, x^+(s))\, ds > 0$$

which is a contradiction. Therefore it follows that $x^+ \in \mathcal{M}_\alpha^+$ is a non-trivial solution of equation (1).

Put $\mathcal{M}_\alpha^- = -\mathcal{M}_\alpha^+$. Clearly, $\mathcal{M}_\alpha^+ \cap \mathcal{M}_\alpha^- = \{0\}$ and by the same argument we obtain another non-trivial solution $x^- \in \mathcal{M}_\alpha^-$ ∎

Remark 10. The previous theorem is the only multiplicity result that we know for equation (1) under the natural growth conditions. In the case of a smooth functional φ, that is in the case of the classical growth conditions many multiplicity results of other types were obtained using critical point techniques (see, for example, [15, 16]). In the last few years some variants of "Non-Smooth" Critical Point Theory have been presented by different authors (see, for example, [2, 18] and the references therein). A variant adopted to the study of the energy functional φ for equation (1) under the natural growth conditions was given in [13]. Unfortunately, the attempts to verify the compactness condition of Palais-Smale type for φ were unsuccessful and the multiple solution problem for the Hammerstein equation (1) under the natural growth conditions is still open.

Remark 11. The results given in the paper can be generalised to Hammerstein equations with kernels having a finite number of negative eigenvalues and also to systems of Hammerstein equations in ideal spaces of vector functions (see [14]).
